Abstract

This study was carried out to determine the flora of the gardens and road sides in Adana from March 2008 to April 2012. During the floristic studies, 337 vascular plant taxa belonging to 259 genera and 93 families were determined. Families with the greatest number of taxa are Asteraceae 35 species (10%), Fabaceae 30 species (9%), Poaceae 20 species (6%), Rosaceae 11 species (3%) and Lamiaceae 10 species (3%). According to the life-forms phanerophytes 134 species (40%) and therophytes 118 species (35%) are more than the others (chamaephytes, hemicryptophytes, and geophytes). Forty-eight percent (162 taxa) of total flora in the area is exotic species and the rest (52%) are indigenous. Total flora consists of 62% (209 taxa) ornamental species and 38% (128 taxa) ruderal species.

Key words: Adana, Urban flora, Exotic species, Native species, Ornamental species

Introduction

Cities play a major role not only as providers of employment, shelter and services but also as centers of culture, learning and technological development and industrial centers for the processing of agricultural produce and manufacturing and portals to the rest of the world (Mulligan & Crampton, 2005; Eskin *et al.*, 2012).

The alteration of ecosystems by humans is most apparent in and around urbanizing landscapes (Lundholm & Marlin, 2006). There is no doubt that human civilization has had a negative impact on biodiversity, especially since the industrial revolution (Shinwari & Qaisar, 2011). Exposure to pollution, disconnection from nature and wildlife, and surroundings of building and other structures can be elements of an urban lifestyle. The world is urbanizing rapidly and more than half of the world's population lives in towns and cities (Knapp *et al.*, 2008).

Cities generally host a higher number of vascular plant species than rural areas of the same size (Wittig & Becker, 2010). Urban habitats are often compared with rural or wilderness areas and are typically characterized by lower species diversity, replacement of native wildlife with non-native species, simplified species composition, increased patchiness of habitat, low stability, and increased landscape conversion towards the urban centre (Turner *et al.*, 2004; Dearborn & Kark, 2010; Malik *et al.*, 2012; Ugulu *et al.*, 2012; Larondelea & Haaseb, 2013).

The destruction of habitats through agriculture and urban sprawl, excessive use of pesticides and artificial fertilizers, overfishing and hunting, and the release of other toxic compounds into the environment are always harmful to the native biodiversity (Smith *et al.*, 2006).

The main objective of this study was to determine the floristic characteristics of plants in the gardens and streets in Adana, Turkey's fourth largest city.

Material and Methods

Study area Adana ($36^{\circ}29' N$, $35^{\circ}32' E$) is a city in the East Mediterranean region of Turkey and a major agricultural and commercial center. The city is located on

both sides of the Seyhan River, extends over an area of *c.* 105 km², 30 km inland from the Mediterranean Sea, in south-central Anatolia (Fig. 1). It is the administrative seat of the Adana Province and has a population of 2.1 million, making it the fifth most crowded city in Turkey. Adana-Mersin Metropolitan Area, with a population of 3 million, stretches over 100 km from east to west and 25 km from north to south; encompassing the cities of Mersin, Tarsus, Adana, and Ceyhan. NATO's Incirlik Air Base is located in town of Incirlik 12 km away from Adana.

The history of Adana goes back more than 3000 years; findings in the region reveal human occupation of the area during the Paleolithic Age. Tepebag Tumulus, where archaeologists found a stone wall and a city centre, was built in the Neolithic Age; it is considered to be the oldest city of the Cilicia region. 6th BC century onwards, Adana was ruled by the Romans. In the mid 7th century, the city was captured by the Arab Abbasids. The Byzantines recaptured Adana in 964. After the Battle of Manzikert (1071), the Seljuk Turks overran much of the Byzantine Empire. From the end of the Renaissance to the modern era (1517-1918), the Ottoman Empire ruled the area.

The territory of the research area; Pliocene limestone, Pleistocene conglomerates, and Holocene alluvial has formed. The residential and agricultural areas of Adana (Cukurova delta / Cilician plain) is mostly a large stretch of flat, fertile land regarded as one of the most agriculturally productive areas of the world.

The Mediterranean climate in the study area is characterized by long summer droughts and mild and rainy winters. The mean annual precipitation is about 465.2 mm, while the monthly precipitation approximates 5.2 mm in August and 117.8 mm in January. The mean maximum temperatures range from 13.3°C in January to 33.9°C in August and the mean minimum temperatures from 5.5°C in January to 24°C in August. The highest recorded temperature was in July with 44.0°C. The lowest recorded temperature was in January -6.4°C. According to the average climatic data for 10 years (2002-2011) obtained from the Meteorological Station of Cukurova University, the dry period for the study area is from May to October (Fig. 2).

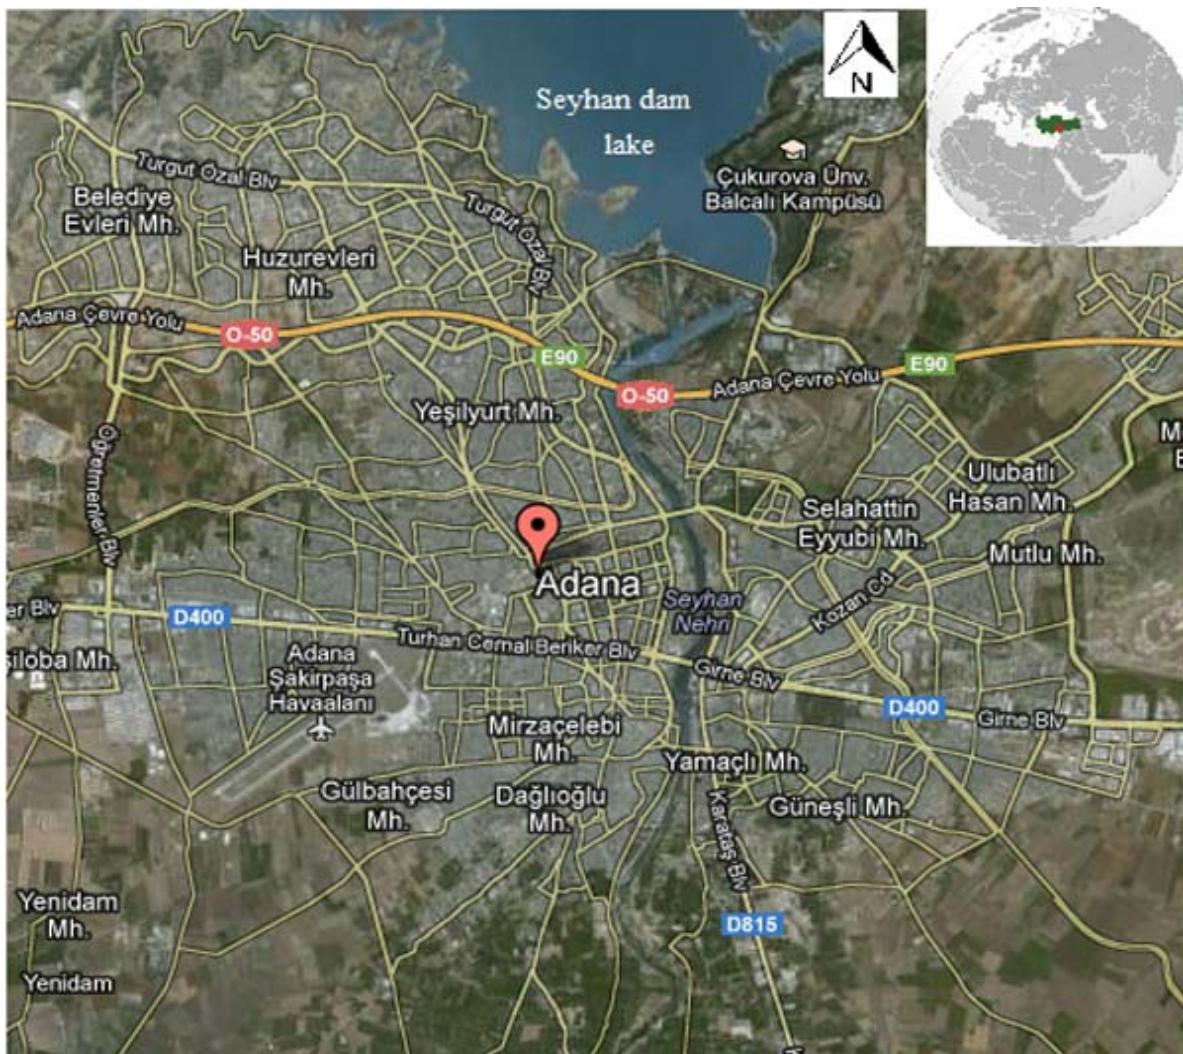

Fig. 1. Geographical position of Adana city center (investigated area).

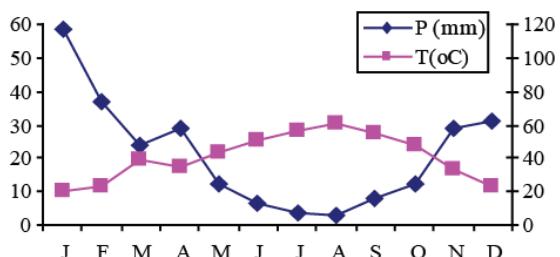

Fig. 2. Ombothermic diagram of the study area. The dry period in May – November, the rainy period (>100 mm / in January, and transitional period in March and April.

Materials of this study were comprised 337 vascular plant samples collected from gardens and road sides of the city of Adana from March 2008 to April 2012. The all specimens collected were dried according to known herbarium techniques and processes. These samples were mainly determined with the help of Flora of Turkey (Davis, 1965-1988; Guner *et al.*, 2000) and other related publications (Barwick, 2004; Forrest, 2006). All collected plant specimens during the study are kept at the

Herbarium of Çukurova University, Faculty of Science and Letters, Biology Department (ADA).

Floristic list, given in Table 1 appended to the end of the text. Families and species of each family are listed in alphabetical order. The naturalness, ornamental status, voucher number and life-form of each species were specified.

Results

During the floristic researches of ruderal and ornamental flora so far conducted on the territory of the city of Adana, it was established the presence of 337 species of vascular plants, divided into 2 divisions, 7 classes, 93 families and 259 genera. The total flora consists of 285 species, 17 subspecies, 20 varieties, 8 hybrids and 7 cultivars. Division Pteridophyta is represented with one species, Division Spermatophyta with 336 species. Pteridopsida, Araucariopsida and Cycadopsida classes are represented by single species, class Pinopsida with 4 species, class Cupressopsida with 6 species, and class Magnoliopsida with 286, while 38 species belong to the class Liliopsida (Table 2).

(Abbreviations: eo, exotic ornamental species for Turkey; nr, native ruderal species (weed species) for Turkey; no, native ornamental species; Th, Therophyte; Ph, Phanerophyte; Ch, Chamaephyte; H, Hemicryptophyte; G, Geophyte)

Table 2. Representation of species, genera and families in the urban flora of the city of Adana.

Class	No. of families	%	No. of genera	%	No. of species	%
Pteridopsida	1	1.07	1	0.40	1	0.30
Araucariopsida	1	1.07	1	0.40	1	0.30
Cycadopsida	1	1.07	1	0.40	1	0.30
Pinopsida	1	1.07	2	0.80	4	1.19
Cupressopsida	1	1.07	3	1.20	6	1.78
Magnoliopsida	79	84.95	207	83.13	286	84.87
Liliopsida	9	9.68	34	13.66	38	11.19
Total	93	100.00	249	100.00	337	100.00

Table 3. The families represented with 10 and more genera in the urban flora of the city of Adana.

Families	No. of species	%
Asteraceae	35	10.3
Fabaceae	30	8.9
Poaceae	20	5.9
Rosaceae	11	3.3
Lamiaceae	10	3.0
Total	106	31.4

The composition of the urban flora of the city of Adana includes 5 families with 10 or more species, where the most numerous are the family Asteraceae with 35 species, family Fabaceae with 30 species, family Poaceae with 20 species, family Rosaceae with 11 species, and the family Lamiaceae with 10 species (Table 3).

The genera including the most species are *Trifolium* (5 species), *Veronica* (5 species), *Ficus* (4 species) and *Euphorbia* (4 species).

The life-form spectrum in the present study showed predominance of phanerophytes (134 spp., 40% of the total flora), followed by therophytes (118 spp., 35%), hemicryptophytes (37 spp., 11%), geophytes (26 spp., 8%) and chamaephytes (22 spp., 6%) (Table 4).

Discussions

The phanerophytes included trees, large woody shrubs, perennial herbs and woody climbers. Therophytes (annuals) are drought evaders in the sense that the whole plant sheds during unfavorable conditions. Phanerophytes are very common in tropical areas and their number decreases towards temperate and polar areas. Therophytes are most abundant in arid climates such as regions with Mediterranean climate. In this study, high rates of phanerophytes and therophytes can be attributed human activities (Reddy & Pattanaik, 2009). Indeed, phanerophytes dominance stemmed from plantation of exotic woody ornamental plants in the research area. Phanerophytes rate of native flora in the region where the research area was 5% (Turkmen & Duzenli, 1990).

The 48% (162 taxa) of total flora in the research area is exotic species and the rest (52%) are indigenous. Total

Table 4. Life form spectrum of urban flora of Adana city.

Life form	No. of species	%
Phanerophyte	134	40
Therophyte	118	35
Hemicryptophyte	37	11
Geophyte	26	8
Chamaephyte	22	6
Total	337	100.00

flora consists of 62% (209 taxa) ornamental species and 38% (128 taxa) weed species. The native ornamental species were represented with 37 species (11%).
